

How GastroMetrics Works

A complete guide to every module, every screen and — above all — every formula the application uses to calculate costs, prices, margins and purchasing suggestions. Meant to be read once from start to finish, and then consulted as a reference.

01 Introduction and general navigation

GastroMetrics is a costing and management system for restaurants: it turns a list of ingredients and quantities into an exact cost per dish, suggests a sale price using two different methods, controls inventory, and generates the purchase orders you need — all kept separate by business, with its own team, permissions and reports.

01.0 Where to start (the first 10 minutes)

This manual is a **complete reference** — it's meant to be consulted, not necessarily read start to finish before touching the app. If this is your first time in, here's the shortest path to seeing a real result, in the same order you'd see it using the application:

- 1 Enter your business.** If it's a new account, the sign-up wizard will already have created one for you (section 02.1); if you manage several, the app always opens on the Dashboard with the full list.
- 2 Load your first ingredients.** From Ingredients, by hand or by importing an Excel file (section 03) — each one with its purchase price and net content. You don't need to load your whole database at once: 3 or 4 are enough to see the system in action.
- 3 Create your first recipe.** In Recipe Sheet (section 05), add those ingredients with the quantity the recipe uses. The production cost is calculated on its own, ingredient by ingredient, in real time.
- 4 Look at the suggested sale price.** The same screen shows you the margin and the final, already-rounded price — that's the moment you see the app's real value: you went from a list of ingredients to a justified sale price, without a separate spreadsheet.

- 5 Export the PDF or keep exploring.** From there you can pull the kitchen sheet or the administrative one (section 09), or move on to Inventory, Menus and Purchase Orders when you need them — they aren't required steps for your first result, they're for once you're already operating with several recipes.

HOW TO USE THE REST OF THE MANUAL

After those 5 steps, the rest of the sections are topic-by-topic reference, not a mandatory continuation: the route table in section 01.2 tells you which section of this document covers each screen in the app, so you can jump straight there when you need to.

01.1 Account structure

An account can manage **several businesses** (up to the limit its plan allows). Each business has its own database of ingredients, recipes, inventory, menus and purchase orders — nothing mixes between businesses even if they belong to the same account. The display currency, on the other hand, is a preference of the account as a whole, not of each business separately.

01.2 The side menu

These are the application's real routes, in the order they appear in the sidebar:

SECTION	ROUTE	WHAT IT CONTAINS
Dashboard	/dashboard	The account's general panel: KPIs, businesses, recent activity, notifications.
Recipe Sheet	/ficha-tecnica	The form for creating or editing a recipe.
My Recipes	/mis-recetas	Listing, search, trash, duplicating/migrating recipes.
Ingredients	/ingredientes	The business's ingredient database.
Inventory	/inventario	Stock records, statuses, snapshot history.
Team	/equipo	Invite people and configure their permissions (only shown if the plan includes it).
Menus	/menus	Building menus by course (starter, main, dessert...).
Purchase Orders	/menu-y-compras	Manual or automatic creation of orders to suppliers.
Reports	/estadisticas	Overview, Sales and Finance.
Businesses	/negocios	Creating, accessing and deleting businesses.
My Plan	/mi-plan	Active plan and subscription management (Stripe).

Settings is **not a page**: it's a modal window accessible from any screen, with tabs for Profile, Appearance, Regional, Notifications and (for the account owner) Developer.

Dashboard — a real screenshot of an account with 2 businesses and 4 recipes. The side menu on the left is the same throughout the app.

NOTE

When you're browsing inside a specific business, most routes append `?business={id}` to the URL — that's what tells each screen which database of ingredients/recipes/inventory to show.

01.3 How the modules connect

Before going into the detail of each screen, here's the full map of how a piece of data flows from entering as an ingredient to leaving as a purchase from a supplier:

Solid arrow = automatic. Dotted arrow = requires a manual action from the user (recording the count, or confirming the order). The Sub-recipes loop is the only point where a Recipe

becomes an Ingredient again.

01.4 The Dashboard

It's the first thing you see when you log in. Three blocks, from top to bottom:

- **What to do today** — three cards that are always actionable (not just informational): ingredients below minimum, recipes with no sale price, and the average margin of the recipes that do have a price. Each one takes you with a single click straight to Inventory, My Recipes or Reports. They're calculated by adding up every business in the account, not one at a time.
- **General KPIs** — total recipes, ingredients, businesses and average cost, with no need to open any specific business.
- **Quick Actions** — one large button per module (Ingredients, Recipe Sheet, My Recipes, Menus, Inventory, Purchase Orders, Reports, and Log Sales/Team depending on the plan), to jump straight in without going through the side menu.

02 Account, businesses, team and plans

Everything in GastroMetrics — recipes, ingredients, inventory — hangs off a "business." This section explains how businesses are created, how they're shared with a team, and what each subscription plan unlocks.

02.1 Creating a business

Setup is a 3-step wizard:

- 1 **Basic information and logo.** Name, description, type of business, and the business logo (optional at this same step — it's compressed in the browser itself before being saved, and appears in the header of the Recipe Sheet, Purchase Order and Invoice PDFs, see section 08.8).
- 2 **Monthly fixed expenses.** Rent, utilities, operational costs, marketing, labor costs and other — these expenses are the base for the fixed-cost allocation that can be added to each recipe's price (see section 05.6).
- 3 **Default costing method.** "GastroMetrics" (6 categories) or "Food Cost %" — the new business inherits this method for every recipe it creates, though it can be changed recipe by recipe.

Available business types:

The theme color is **not** requested in this wizard — it's configured afterward, inside the business's own panel (/business/[id]). It's chosen from 12 curated palettes and is what colors the accents on those same PDFs:

02.2 Switching businesses

There's no single dropdown selector: the **Businesses** page shows one card per business with an "Access" button that opens its own panel. While you're inside any module, the sidebar also shows the full "My businesses" list so you can jump from one to another without going back to the Dashboard.

02.3 Team

Inviting someone sends a real email with an access link. Unlike other systems, **there are no named roles** (there's no "admin" or "editor" label) — instead, each invited person is configured with three independent controls:

CONTROL	OPTIONS
Scope	"Dashboard" (sees every business in the account) or a single specific business only.
Allowed tools	Independent checkboxes: recipes, ingredients, shrinkage, manual purchase orders, automatic purchase orders, inventory, menus, overview statistics, manual sales, finance, and "team" (delegating administration of the team itself).
PDF access	None / Client (kitchen sheet, no costs) / Administrative (with costs and margins).

The owner can turn on a "Preview" to see the application exactly as that person would, with their same permissions. The maximum number of team members is 3 by default (expandable). Access to each member's features is evaluated **only** by what's been marked for them — the account's plan doesn't matter once someone has signed in with a team invitation.

02.4 Subscription plans

PLAN	PRICE	BUSINESSES	USERS	WHAT IT ADDS OVER THE PREVIOUS TIER
Foodie	Free	1	1	Recipes, ingredients and kitchen PDF (these three are included in <i>every</i> plan, including this one).
Home Cook	\$15/mo	1	1	Shrinkage management, manual purchase orders, administrative PDF, customer invoicing (see 08.8).
Chef de Partie	\$35/mo	1	1	Automatic purchase orders (auto-suggest), Inventory, Menus, Reports → Overview, Sales (manual log, see section 09).
Sous Chef POPULAR	\$70/mo	2	2	Reports → Finance (P&L, Menu Engineering, POS import).
Chef Ejecutivo	\$120/mo	5	5	Team (invite people with independent permissions).

HOW IT'S ENFORCED

When a feature is locked, the app shows one of two distinct messages: "your plan doesn't include this" (with a button to My Plan), or "the account owner restricted this for you" — if you're using the app under a team invitation.

02.5 Billing

Plan payment is processed with Stripe Checkout. On returning from payment, the application confirms the session against Stripe (never against an editable URL parameter) before activating the plan. Changes and cancellations made directly from the Stripe Customer Portal are also synced automatically to the account via Stripe notifications (webhooks) — there's no need to come back to the app for them to take effect.

When you cancel from the Customer Portal, Stripe by default doesn't cut access instantly — it keeps it active until the end of the already-paid period. In the meantime, "My Plan" shows a notice: "**Your subscription is cancelled — you still have full access until [date]**", confirming that the cancellation was indeed recorded, without having to wait for the period to end to find out.

02.6 Account and access

Sign-up is a 5-step wizard: details and password, professional information (country/currency, business type and size), **choosing a plan**, terms confirmation, and the final summary. The plan step shows all 5 real plans — Chef Ejecutivo appears with its full description but is greyed out and can't be selected ("Available for businesses"), because that plan isn't self-

service (see 02.4). If you arrive from /planes with a plan already chosen, that plan comes pre-selected. Sign-in is email and password — there's no social login. Full email-based password recovery is available.

That same last step has an optional checkbox, unchecked by default: **"I want to receive product news by email."** It can be changed at any time afterward, from Settings → Notifications → "Product news."

02.7 Seeing an example before you start

On the main Dashboard, if there isn't a single recipe yet, the option **"See an example first"** appears: it creates a real ingredient and a real recipe (with cost and price already calculated), and opens the Recipe Sheet directly so you can see the calculation working before writing anything of your own. It's entirely optional and can be deleted at any time — it's never created without explicitly asking for it with that button.

02.8 Product news

On login, if there's an update you haven't seen yet, a window appears with the most recent changes (only once per update). If you checked the box in section 02.6, you'll also get an email with the same content whenever the GastroMetrics team decides to send it — it's never automatic on every update, so there can be updates with no email.

02.9 Deleting your account

From Settings → "Account" tab, you can delete the account entirely — permanently, by typing your email to confirm. It first cancels any active real Stripe subscription (so an account that no longer exists doesn't keep getting billed), and cascades the deletion to every business, recipe, ingredient, inventory record, menu and purchase order. There's no way to undo it afterward.

Settings → Account — the "Account" tab is the only one of the five with a destructive action; it requires typing your email to confirm before deleting anything.

03 Ingredients

The ingredient database is the foundation of all costing: every recipe consumes ingredients from here, and every price change automatically propagates to every recipe that uses it.

03.1 Fields of an ingredient

Name, category, unit of measure, supplier, purchase packaging (optional), and a price block with four values: **purchase price** (what's paid for the whole package — e.g. a sack), **net content** (how much of the base unit that package holds — e.g. 25,000 g), **unit price** (calculated automatically: $\text{purchase price} \div \text{net content}$), and the date of the last update.

BASE UNIT PRICE

$$\text{unit_price} = \text{purchase_price} \div \text{net_content}$$

This is the number actually used to cost recipes — never the price of the whole package directly.

03.2 Categories (fixed list)

You can't create new categories: you have to pick one of these 35.

Oils Alcohol Poultry Beverages Coffee Pork Chocolate Game
Disposables Sweets Cured Meats Extracts Spices Noodles / Pasta
Edible Flowers Fruit Grains Fats Garnish / Sides Flour Herbs Eggs
Dairy and Derivatives Yeast Shellfish Dough Molecular Nuts Other Fish
Pastry Beef Salt Dry Goods Syrups Vegetables

Sub-recipe / production (Mise en place)

The last category on the list isn't picked by hand: it's the one automatically assigned to "ingredients" created from a sub-recipe (see section 06).

03.3 Units of measure

Grams Kilograms Milliliters Liters Ounces Fluid Ounces Pounds
Gallons Unit

The distinction between "unit" and the rest matters: several of the app's calculations (the suspicious-yield warning, the valuation of "pieces") treat ingredients measured in "unit" specially, precisely because they're countable pieces (eggs, cans) rather than a continuous mass.

03.4 Purchase packaging

When an ingredient is bought in packages (Box, Sack, Bottle, Can, Bag, Jar...), the packaging record stores how much base-unit quantity each package holds. This is what lets a Purchase Order say "4 Boxes" instead of a quantity in grams that nobody would actually order that way in practice.

03.5 Everything separated by business

The ingredient database is exclusive to each business — switching businesses shows a completely different list. The full database can also be imported/exported in Excel, with a template generated dynamically from the app's real categories and units.

03.6 Shrinkage

HOME COOK+

Shrinkage is the part of an ingredient that's paid for but can't be used (peeling, bone, trimmings, evaporation). GastroMetrics doesn't treat it as a loose field: it's a dedicated screen ("Manage Shrinkage," from Ingredients) with a master switch that turns the whole system on or off, and — per ingredient — a "Global" mode (uses its category's default %) or a "Custom" mode (its own %, or a fixed amount subtracted instead of a percentage).

Some default percentages by category, from a longer table: Shellfish 63%, Fish 52%, Beef 33%, Poultry 27%, Fruit 24%, Vegetables 21% — many categories (dry goods, packaged items) start at 0%.

ACTUALLY USABLE CONTENT

```
if Global:                adjusted_content = original_content × (1 -  
category_%/100)  
if Custom (%):            adjusted_content = original_content × (1 -  
own_%/100)  
if Custom (fixed amount): adjusted_content = original_content -  
fixed_amount
```

REAL EFFECT ON THE INGREDIENT'S COST

```
ingredient's new "net content" = adjusted_content  
ingredient's new "unit price"   = purchase_price / adjusted_content
```

This raises the real cost per unit (you paid for the original content, but only get to use the adjusted amount) and **directly rewrites** the ingredient's unit price — it isn't a separate adjustment calculated "on the fly." That's why shrinkage's effect shows up automatically everywhere with no extra logic: in the extended cost of every recipe that uses that ingredient (05.3), in the chain recalculation (04.5), and in any PDF — they all read that same, already-adjusted unit price. Turning off the master switch restores each ingredient's original content and price.

03.7 Deleting an ingredient

Before confirming, the delete dialog shows which recipes use that ingredient — if there are any, the full list of names appears, with a notice that those recipes will be left with a missing ingredient. It's purely informational: deletion isn't blocked, but it's no longer a surprise afterward.

Deleting an ingredient — the red notice lists every affected recipe by name before the deletion is confirmed.

04 Inventory

Inventory isn't just "how much stock is left" — it's a history of counts (snapshots) that also feeds back into ingredient prices and triggers chain recalculations on the recipes that use them.

04.1 Item status: critical, low, normal

Every ingredient in inventory has a **configurable minimum** (`minStock`), editable directly from the table. The status is recalculated with this rule, always in this order:

STOCK STATUS

```

if current_stock ≤ minimum           → CRITICAL
if current_stock ≤ minimum × 2       → LOW
otherwise                             → NORMAL

```

If an ingredient has never been counted yet (`current_stock` empty), it's treated as **Normal** by default — it isn't flagged critical just for lack of data.

● Critical — stock $\leq$ minimum

● Low — stock $\leq 2 \times$ minimum

● Normal — above $2 \times$ minimum

Inventory — "Eggs" with a stock of 5 and a minimum of 5 is flagged in red ($5 \leq 5 \rightarrow$ Critical), and the "Critical Products" counter climbs to 1.

04.2 Register Inventory: the three types

"Register Inventory" creates a **snapshot in time** of the stock, and also updates the real current stock. There are three types, built for a concrete workflow:

TYPE	WHEN IT'S USED
Initial Inventory	A physical count at the start of a period (e.g. start of shift or of the week).
Final Inventory	A physical count at the close of a period, to compare against the initial one.
New Purchase	Recording merchandise that just came in. It's the only type that asks for a "price paid," the only one that recalculates the weighted average cost, and the one that can trigger a chain recalculation of recipe costs if the price changed.

The count can be captured two ways: directly in the base unit (e.g. grams), or "by packaging" (e.g. "3 sacks"), and the system does the conversion: $\text{base_quantity} = \text{packaging_quantity} \times \text{net_content}$.

04.3 Valuation

VALUE OF A LINE / OF THE WHOLE INVENTORY

$\text{line_value} = \text{current_stock} \times \text{price}$

$\text{Total Inventory Value} = \sum \text{line_value} \text{ (across all ingredients)}$

04.4 Weighted average cost

Every time a "New Purchase" is registered, the app infers how much was bought (the stock increase compared to the previous count) and recalculates a cumulative weighted average. This average is purely an informational valuation figure — actual recipe costing always uses the unit price from the *most recent* recorded purchase, not the average.

04.5 Chain recalculation

If recording a purchase changes an ingredient's price, GastroMetrics automatically recalculates the cost of **every** recipe (and sub-recipe) that uses that ingredient, and tells you how many were affected — there's no need to open recipes one by one to keep the numbers up to date.

05 Recipes and Recipe Sheet

This is the heart of the application: it turns a list of ingredients with quantities into an exact cost, and that cost into a suggested sale price, with full transparency about how every number was reached.

05.1 Form fields

- **Name** — free text.
- **Classification** — one of 17 fixed options (see table below). It decides whether a recipe is treated as a sub-recipe.
- **Course** — which moment of service it belongs to (Starter, Main Course, Dessert...), 34 fixed options.
- **Yield** — how much the recipe produces (e.g. "8" portions, or "1,200" grams), with a unit selector next to it (servings/g/kg/ml/L/oz/lb/unit — "g" by default). That unit is what prints next to the number on the PDF.
- **PAX Modifier** — lets you scale the recipe to a different number of diners without touching the original values (see 05.4).
- **Image** — drag and drop, or select a file.
- **Ingredients** — a search box that filters the business's ingredient database. It only lets you pick ingredients that already exist; you can't create a new ingredient from here.
- **Procedure and Notes** — a numbered list of preparation steps.

HOW TO NEST A RECIPE INSIDE ANOTHER

There's no "add sub-recipe" button: you get there by giving a recipe the "Sub-recipe" classification, saving it, and from that point on it automatically appears in the same ingredient search box on any other sheet (see section 06).

Recipe Sheet — this real example triggers exactly the warning from section 05.4: declared yield of "2," but an ingredient with a quantity of "150" ($150 \geq 2 \times 20$).

05.2 The 17 classifications

Hot Line (Cuisine chaude)

Cold Line (Garde-manger / Cuisine froide)

Sauces and Stocks (Saucier)

Fish (Poissonnier)

Meats and Roasts (Rôtisseur)

Grill (Grillardin)

Fried Foods (Friturier)

Vegetables and Sides (Entremetier)

Bakery (Boulangerie)

Viennoiserie

Pastry (Pâtisserie)

Chocolate and Confectionery

Ice Cream (Glacerie)

Charcuterie and Cured Goods

Fermentation and Preserves

Sub-recipe / production (Mise en place)

R&D

05.3 Production Cost

Every ingredient line has an "extended cost": what that exact quantity costs within the recipe.

EXTENDED COST OF AN INGREDIENT

$$\text{extended_cost} = \text{quantity} \times \text{ingredient_unit_cost}$$

PRODUCTION COST

$\text{Production Cost} = (\sum \text{extended cost of each ingredient}) \times \text{PAX_multiplier}$

05.4 Yield, yield by weight, and PAX

PAX MULTIPLIER

$\text{base_yield} = \text{declared_yield}$ (or 1 if there isn't one)

$\text{PAX_multiplier} = \text{desired_PAX} / \text{base_yield}$ (if a PAX was activated)

$\text{PAX_multiplier} = 1$ (if no PAX was used)

When it's activated, each ingredient's quantities are rescaled and always rounded **up** to one decimal place — the app never leaves you short in the kitchen because of rounding.

YIELD BY WEIGHT (ESTIMATED)

$\text{Yield by weight} = \sum \text{quantities of ingredients measured in g / ml / kg / l}$

This is the number that appears as "Est. yield by weight" in the administrative PDF. It serves as a fallback when the recipe has no declared yield in portions.

EFFECTIVE YIELD (THE ONE USED IN EVERY CALCULATION)

if there is a declared yield $\rightarrow \text{declared_yield} \times \text{PAX_multiplier}$

otherwise $\rightarrow \text{yield by weight (estimated)}$

UNIT COST

$\text{Unit Cost} = \text{Production Cost} / \text{Effective yield}$

SUSPICIOUS YIELD WARNING

If the quantity of *any* ingredient measured in "unit" is 20 times (or more) the declared yield, the app shows a yellow warning both in the form and in the administrative PDF: "the declared yield looks very low compared to the quantity of some ingredient." It's only a warning — it never blocks saving or exporting. It came from a real case: a recipe with a declared yield of "1 g" that used 200 eggs.

$\text{max_quantity_in_\"unit\"} \geq \text{declared_yield} \times 20 \rightarrow \text{warning is shown}$

05.5 The two pricing methods

Every recipe uses one of these two methods (the business sets a default method, but it can be changed recipe by recipe):

The "GastroMetrics" method (6 categories)

Splits the production cost into six categories, each expressed as a percentage of the production cost — not of the sale price:

CATEGORY	DEFAULT %
Utilities	10%
Marketing	10%
Operational Costs	30%
Labor Costs	25%
ISV (tax)	0%
Net Profit	30%

All the percentages are editable per business. A seventh, non-percentage amount can be added on top of these six: the **allocated fixed cost** (see 05.6).

EACH CATEGORY

$$\text{category_amount} = \text{Production Cost} \times (\text{category_}/100)$$

SALE PRICE — 6-CATEGORY METHOD

$$\text{unit_profit} = (\text{sum of the 6 categories} + \text{allocated fixed cost}) / \text{Effective yield}$$
$$\text{Sale Price} = \text{round_up_to_multiple_of_5}(\text{Unit Cost} + \text{unit_profit})$$

"Round up to the nearest multiple of 5" always rounds up, never to the nearest — a cost of 61 rounds to 65, not to 60. It's the only rounding step in the entire pricing flow.

The "Food Cost %" method

Simpler: you fix what percentage of the sale price you want the ingredient cost to represent (typical target: 28-35%), and the price is derived from that.

SALE PRICE — FOOD COST % METHOD

$$\text{Sale Price} = \text{round_up_to_multiple_of_5}(\text{Unit Cost} / (\text{target_}/100))$$

Example: unit cost 20, target food cost 30% → $20 \div 0.30 = 66.67$ → rounds up to 70 (never down to 65).

SIDE BY SIDE: SAME UNIT COST, BOTH METHODS

"GastroMetrics" method (6 categories, default values – Unit Cost = 20, Effective Yield = 1):

$$\text{unit_profit} = (2 + 2 + 6 + 5 + 0 + 6) / 1 = 21$$

$$\text{Sale Price} = \text{round_up_to_multiple_of_5}(20 + 21) = 45$$

"Food Cost %" method (target 30%, same Unit Cost = 20):

$$\text{Sale Price} = \text{round_up_to_multiple_of_5}(20 / 0.30) = 70$$

Same unit cost, two different prices — that's not a bug: each method distributes profit differently. The 6-category method gives granular control per cost category (each one is adjustable on its own); Food Cost % is a single number, simpler to explain and the more common one in the restaurant industry. The business picks a default method (02.1) and can change it per recipe at any time (05.5) — no data is lost when switching, since both are calculated from the same real Production Cost.

05.6 Allocated fixed cost

If the business set up monthly fixed expenses (section 02.1) and an estimate of how many dishes it sells per month, that expense is automatically spread across the dishes and added as one more line of the price — with no need to write it in recipe by recipe.

$$\begin{aligned}\text{fixed_cost_per_dish} &= \text{business_monthly_fixed_expenses} / \\ &\text{estimated_monthly_dishes} \\ \text{allocated_fixed_cost} &= \text{fixed_cost_per_dish} \times \text{Effective yield}\end{aligned}$$

05.7 Margins and sheet statistics

TOTAL SALE PRICE

$$\text{Total Sale Price} = \text{Final Sale Price} \times \text{Effective yield}$$

CONTRIBUTION MARGIN

$$\text{Contribution Margin \%} = (\text{Total Sale Price} - \text{Production Cost}) / \text{Total Sale Price} \times 100$$

FOOD COST % (REAL FOOD COST, INFORMATIONAL)

$$\text{Food Cost \%} = \text{Production Cost} / \text{Total Sale Price} \times 100$$

NET PROFIT (TOTAL FOR THE BATCH) VS. UNIT PROFIT

$$\text{Total Net Profit} = \text{Total Sale Price} - \text{Production Cost}$$

$$\text{Unit Profit} = \text{Total Net Profit} / \text{Effective yield}$$

05.8 Overriding the price or the profit by hand

The suggested price is never mandatory. You can write in a manual **Unit Profit** directly (and the 6-category method's price is recalculated from it), or a manual **Sale Price** directly, which then takes over everything downstream — Total Sale Price, Contribution Margin, Food Cost % — without touching Production Cost or Unit Cost, which always reflect the real ingredient data.

05.9 Duplicate, Migrate and Trash

Duplicate

Creates a copy within the **same** business, with a new identifier and the suffix "(Copy)" in the name.

Migrate

Moves the recipe to another business in the account, dragging along every sub-recipe and their ingredients in a chain — reusing any matching ingredient that already exists at the destination, instead of duplicating it.

Deleting a recipe sends it to the **Trash**, it isn't removed instantly: it stays recoverable for **30 days** before being purged automatically. It can also be permanently deleted before that deadline.

05.10 Saving, exporting and generating purchases with PAX active

While the PAX Modifier has a value, everything you see on the Recipe Sheet — ingredient quantities, Production Cost, Effective Yield — is a **live preview**: the recipe saved in the database doesn't change until you press "Save". Three actions use that preview in different ways.

There are no separate buttons "Save as new yield" or "Save temporarily" — it's the same "Save Recipe" button as always. The difference is that, if PAX is active when you press it, the app intercepts the save with the confirmation dialog below before continuing.

EXPORTING A PDF WITH PAX ACTIVE

"Export PDF" exports the document already scaled (quantities and yield multiplied) without saving anything. While PAX is active, the button shows a "Scaled to N" notice so it's clear, before exporting, which version you're about to print. Closing the dialog or leaving the page without saving leaves the real recipe untouched.

GENERATING A PURCHASE ORDER WITH PAX ACTIVE

The "Generate Purchase Order" button (next to "Export PDF") builds the order with quantities already scaled to the active PAX — same "Scaled to N" notice before you click (see 08.7) — also without saving the recipe.

SAVING WITH PAX ACTIVE PERMANENTLY OVERWRITES THE BASE YIELD – WITH CONFIRMATION

Saving while PAX is active asks for confirmation first: the recipe is about to be saved at the new size, and the current yield is frozen as the "original" so it can be restored later. Cancel saves absolutely nothing. Confirming persists the already-scaled recipe as if it were the normal version — Yield and ingredients stay at the new size — and freezes the previous size **only the first time** this happens: scaling and saving again later doesn't overwrite that original, so "Restore original recipe" always goes back to the recipe's real size, no matter how many times it gets rescaled and saved in between.

RESTORE ORIGINAL RECIPE

```
Yield          ← saved_original_yield
Ingredients     ← saved_original_ingredients
PAX Modifier   ← 0
```

The "Restore original recipe" button only appears if the recipe has a saved original (that is, if it was ever saved with PAX active). Restoring **doesn't save by itself** — it leaves the form at the original size, and you still need to press "Save" to confirm it, just like any other edit.

CAREFUL: EDITING THE YIELD BY HAND WHILE PAX IS ACTIVE

The PAX Modifier isn't a fixed multiplier — it's a *target size*. With PAX = 12 and Yield = 4 (×3 multiplier), changing the Yield field directly to 6 without touching PAX makes the app recalculate the multiplier to keep targeting 12 (×2 multiplier) — the scaled quantities on screen change even though PAX itself wasn't touched. And if you then press "Restore original recipe", that manual Yield edit is **lost without warning**: Restore always goes back to the saved original (the one from before the first time it was saved with PAX), ignoring any change made afterward, whether to the Yield, an ingredient, or PAX itself. To keep a manually edited Yield, save it with PAX at 0 before touching PAX, rather than relying on Restore.

06 Sub-recipes

A sub-recipe is an intermediate preparation (a base sauce, a stock, a dough) that isn't sold on its own, but is needed in quantity within other dishes. GastroMetrics treats it specially throughout the system.

06.1 How it's activated

Just give the recipe the "**Sub-recipe / production (Mise en place)**" classification. When you save it, the application automatically creates (or updates) a "mirror" ingredient in the same business's Ingredients database, so that sub-recipe can be searched for and added inside any other sheet exactly like a purchased ingredient.

06.2 Usage Cost

The value carried over to the mirror ingredient is the **Usage Cost**: how much a single unit of that sub-recipe's yield costs.

$$\text{Usage Cost} = \text{Sub-recipe's Total Cost} / \text{Sub-recipe's Yield}$$

This is the number that appears as `unitCost` when another recipe uses it as an ingredient — its own "extended cost" and "Production Cost" (section 05.3) are calculated exactly the same way as with any other purchased ingredient, using this usage cost.

06.3 What a sub-recipe does NOT have

Since it isn't sold directly to a diner, everything related to sale price is hidden for it, both in the calculation form and in the administrative PDF:

- No breakdown of the 6 costing categories (marketing, net profit, etc.).
- No Unit Sale Price or Total Sale Price.
- No Contribution Margin or Food Cost % statistics (those numbers only make sense against a real sale price).

Its summary is reduced to three figures: **Production Cost**, **Yield** and **Usage Cost**.

06.4 Chain recalculation

If the cost of a base ingredient inside a sub-recipe changes, its Usage Cost is recalculated, and that new cost is automatically propagated again to every "final" recipe that uses that sub-recipe — with no need to reopen any sheet by hand.

06.5 Watch out for quantities

Because a sub-recipe's usage cost is usually a large number (it represents a full production batch), a badly typed quantity when using it in another recipe (e.g. "150 units" instead of "150 grams") can inflate the total cost to absurd figures with nothing automatically stopping it on save — that's why the suspicious-yield warning (05.4) and the administrative PDF's warnings (section 09.1) exist.

07 Menus

A menu groups already-created recipes into "courses" or service moments (Starter, Main Course, Dessert...) to build a menu or an event.

07.1 Structure

A menu has **courses** (each with a name and order — by default it starts with Starter, Main Course and Dessert, but they're free to rename, delete or add) and **dishes** within each course. Each dish stores: the recipe it represents, an optional price of its own (if not set, it uses the sale price from the Recipe Sheet), and a switch to temporarily disable it without removing it from the menu.

07.2 Menu types

Lunch

Dinner

Brunch

Buffet

Tasting

Catering

Special Event

Other

07.3 Creating a menu (4-step wizard)

- 1 **Details.** Name, menu type, service date (optional) and planned number of diners.
- 2 **Courses.** Naming/adding/removing the menu's courses.
- 3 **Dishes.** One tab per course; the app first suggests recipes whose "Course" field matches, and below that shows the rest of the available recipes.
- 4 **Review.** A complete summary, with the option to set how many portions of each dish are needed for that specific run of the menu (without altering the original recipe).

07.4 Average Price

MENU AVERAGE PRICE

dish_price = dish's own price (if set) or the recipe's sale price

Average Price = $\sum \text{dish_price}$ (active dishes only) / number of active dishes

It's an average per dish, not the total sum — disabled dishes count neither in the sum nor in the divisor.

The screenshot displays the 'Menu Management' interface. At the top, there's a navigation bar with a 'Back to Dashboard' link, a 'Menu Management' title, and a '+ Create New Menu' button. Below this, three summary cards show '1 Menus Created', '1 Total Dishes', and '0 Custom Prices'. A 'Search and Filters' section follows, with a search bar. The main content area shows a menu card for 'almuerzo' (lunch) set for 'Sep 01, 2026'. It lists '3 courses' (Entrada, Plato fuerte, Postre) and '1 dish'. The 'Average Price' is displayed as 'L 50.00'. At the bottom of the menu card are 'View' and 'Edit' buttons.

Menus — the "lunch" menu with 3 courses (Starter, Main Course, Dessert) and 1 active dish; Average Price = L 50.00 because today only one dish is enabled.

07.5 Exporting the menu

From the menu you can export a PDF (see section 09.3, two variants: Client and Internal) or generate a Purchase Order directly with everything needed to produce that menu (see 08).

08 Purchase Orders

A purchase order tells a supplier exactly what and how much to buy. It can be built by hand, generated from a menu, or the app can suggest it on its own by looking at inventory.

08.1 Statuses

Pending

Approved

Ordered

Received

Cancelled

IMPORTANT

There's no mandatory sequence between these five statuses — they can be freely changed in any order, and marking an order "Received" **does not update inventory automatically**. If the received stock needs to be reflected, it has to be recorded separately in the Inventory module.

RECOMMENDED FLOW WHEN RECEIVING GOODS

- 1 Mark the Purchase Order as "Received" (keeps a record of what was ordered and when).
- 2 Go to **Inventory** → **New Purchase** and record what actually came in — quantity and price paid, which can differ from what was ordered.
- 3 That entry is what actually moves stock and recalculates the weighted average cost (04.4); if the price changed, it triggers the chain recalculation across every recipe that uses that ingredient (04.5).

08.2 Auto-suggest by low stock

Available from the Chef de Partie plan. It scans inventory and builds a complete, pre-filled order in seconds, without saving anything until it's confirmed.

WHICH INGREDIENTS QUALIFY

every ingredient with LOW or CRITICAL status is suggested

SUGGESTED QUANTITY PER INGREDIENT

`restock_target = minimum × 2`

`quantity_to_order = max( restock_target - current_stock , minimum )`

It restocks up to double the configured minimum (not just up to the minimum) to leave a margin before falling back into alert status; it never suggests ordering less than the minimum itself, even if the calculated shortfall would be smaller.

Purchase Order List

NAME	DATE	STATUS	ITEMS	TOTAL	ACTIONS
No purchase orders available					

Purchase Orders — the "Auto-suggest by low stock" button already flags 1 (the same critical Eggs from Inventory); below, a real approved order with its PDF, Duplicate and Edit actions.

08.3 Manual creation

You search for the ingredient in the database, and the app auto-fills its unit, supplier and unit price (all editable). The cost of each line is recalculated live as you type the quantity.

08.4 How a line's cost is calculated

COST OF AN ORDER LINE

$$\text{line_cost} = \text{quantity (in base unit)} \times \text{base_unit_price}$$

The purchase packaging ("4 Boxes") is purely informational — it tells you how many packages to buy (always rounding up: $\text{quantity_needed} \div \text{net_content}$), but the line's real cost is always calculated on the base unit, never by multiplying the full package price by the quantity.

ORDER TOTAL

```
subtotal = Σ line_cost (across all items)
```

tax = subtotal × (tax_%/100) (0% by default, editable)

```
Total    = subtotal + tax
```

08.5 Grouping by supplier

Items are sorted alphabetically by supplier, with items that have *no* assigned supplier always at the end — so you can call each supplier once with their complete list. (When the order is

generated from a Menu, there's also an alternative view grouped by ingredient category, simulating the physical walk-through of a storeroom.)

08.6 Duplicate and Edit

Duplicate copies every item with a new date and number (keeping the same status the original had). Edit reopens the same form with the existing data and replaces the order in place when saved.

08.7 Generate from a recipe (Recipe Sheet)

From any recipe's Recipe Sheet, the "Generate Purchase Order" button builds an order from that recipe's ingredients in one click — the same calculation source as "from a Menu" (see 07.5), just with a single dish instead of every dish in the menu. If the PAX Modifier is active at that moment (see 05.10), the order is generated already scaled to that size, with no need to save the recipe first.

SUGGESTED QUANTITY PER INGREDIENT (FROM A RECIPE)

```
quantity_to_order = max( recipe_quantity × PAX_multiplier - current_stock
, 0 )
```

Same as an order generated from a Menu: it subtracts what's already in inventory and uses the ingredient's real, current price and supplier, not the ones saved in the recipe.

08.8 Customer invoicing

HOME COOK+

Different from "Plans and billing" (02.5, which is paying for your own GastroMetrics subscription) — this is the invoice the business hands to ITS customer. It lives as the "Invoices" tab of the Sales module, next to the "Log Sales" tab (see 08.9) — both ways of logging a real sale share the same page. Each line is filled in by picking an existing recipe or menu (pre-fills description and suggested price, same as in the Log Sales tab) or by hand. Auto-generated sequential number, editable tax % (0% by default), notes, live subtotal and total. The business logo and name (02.1) appear in the PDF header.

NOT AN OFFICIAL TAX INVOICE

This document is a real bill for the customer, but it doesn't include a tax authority number, fiscal registration, or any country-specific electronic invoicing integration. Check your country's invoicing requirements before using it as a tax receipt. The same notice, in shorter form, is printed at the bottom of every PDF page.

Every saved invoice is also automatically reflected as a real sale in Reports → Finance (see 10.2) — its revenue counts toward real food cost and Menu Engineering without logging it twice. The amount that counts there is the **subtotal** (without tax), so the real food cost isn't inflated. In the Finance history, that row is marked with an "Invoice" badge linking back to the invoice — and it's only deleted from the invoice itself, not from there.

08.9 Sales CHEF DE PARTIE+

Its own module in the sidebar (no longer a tab inside Reports), with two tabs: "Log Sales" and "Invoices" (see 08.8) — both are ways of logging a real sale, so they share a module. The Log Sales tab combines two ways to log sales directly:

- 1 **Manual entry.** For businesses without a point-of-sale (POS) system: pick an existing recipe or menu directly and the quantity sold; the app calculates the revenue and theoretical cost on its own from the data it already has.
- 2 **Import POS sales.** The same trigger that already existed inside Finance (see 10.2) — it also lives here so you don't have to go into Reports just to upload a file.

Both tabs feed the same history: any sale logged here (manual, POS or invoice) shows up immediately in the **Sales history** at the bottom of this page (day/week/month/year breakdown, exportable to PDF) and also in Reports → Finance. The real analysis of what those sales mean (real vs. theoretical food cost, Menu Engineering, P&L) still lives in Reports → Finance — this page is where a sale gets **logged**, that one is where it gets **read**.

09 PDF Export

Five PDF generators cover the five document types a business needs — recipe sheet, inventory, menu, purchase order and invoice — but several of them produce more than one variant depending on the audience, for a total of **8 distinct documents**: Recipe Sheet (Administrative / Employee / Quick Sheet), Inventory (1), Menu (Client / Internal), Purchase Order (1) and Invoice (1). The same document never serves both the owner and the client.

09.1 Recipe Sheet — three variants

VARIANT	FOR WHOM	WHAT IT INCLUDES
ADMINISTRATIVE	Owner / management	Every data point: ingredients with cost and extended cost, breakdown of the 6 categories, bar and pie charts, margin and food cost statistics. On sub-recipes, this sales panel is hidden entirely (section 06.3).
EMPLOYEE	Kitchen	A "cookbook-style" sheet: name, classification, yield, photo, ingredients (no costs) and procedure. No money figures at all.
QUICK SHEET	Outside parties (supplier, partner)	For sharing externally: name, classification, yield, photo, ingredients and a brief procedure. No costs or sale price — designed not to expose the business's financial information.

AUTOMATIC WARNINGS ON THE ADMINISTRATIVE PDF

Before printing six-digit figures with no context, the sheet checks two signals and, if it finds them, adds a visible notice at the top of the document:

- The production cost exceeds the configured sale price.
- The declared yield looks very low compared to the quantity of some ingredient (the same rule from section 05.4).

09.2 Inventory

A single design, always administrative: a general summary (registered products, total value, number of critical/low items), value distribution by category (pie chart — omitted if there's only one category, so it doesn't draw a single-color circle), top products by value, and the full table with status highlighted in red/amber.

09.3 Menu — Client vs. Internal

Client

The menu the diner sees: serif typeface, plenty of white space, no tables or grids, no cost or margin data whatsoever. The headers for each course use light letter-spacing, in the style of a printed menu.

Internal

For the owner: a cost/price/margin table per dish, plus a bar chart (margin per dish) and a pie chart (total price composition). Reflects the business's theme color.

09.4 Purchase Order

A single operational design: general details (date, status, number of items), the complete table of ingredients to buy with supplier, quantity, cost and extended cost (highlighting in red items with no assigned supplier), the order total, and — if there's more than one supplier — a chart showing the spend distribution by supplier.

09.5 Invoice

A single customer-facing design: business logo and name, customer details, the line-item table (description, quantity, unit price, amount), subtotal, tax and total. At the bottom of every page, in small print, the notice that it's not an official tax invoice (see 08.8).

10 Reports and Numbers

Two tabs, each unlocked by a different plan. (Logging sales itself — manually or imported from a POS — lives in its own module, see 08.9; this is where what those sales mean gets analyzed.)

10.1 Overview

CHEF DE PARTIE+

General counts (recipes, ingredients, menus, orders), inventory value and items in alert, average food cost % and margin, recipes by classification, most-used ingredients, best and worst margin per recipe, sub-recipe usage, ingredients with the most inventory value, and each ingredient's price history with its percentage change since the first record.

10.2 Finance

SOUS CHEF+

Profit and loss statement (P&L), sales import from an external POS system, Menu Engineering analysis (classifies each dish into Stars / Cash Cows / Puzzles / Dogs based on its margin and popularity), and tracking of price variation by supplier.

Import POS sales accepts .xlsx, .xls, .csv and .txt files. The column mapping (which is dish, quantity, date, price) is saved as a **named template** — for example "Toast" or "SoftRestaurant" — and the next time a file with the same headers is uploaded, the app recognizes on its own which template to use and jumps straight to the review step. Several templates can be saved per business (useful if more than one POS system is used, or if you switched from one to another), and unused ones can be deleted.

Two cases that tend to break an import in other systems are covered here: **ambiguous dates** (a POS that exports "03/04/2026" — the app detects whether it's day/month or month/day by looking at the column's real values, with a selector to correct it by hand and a preview of how the first date is being interpreted) and **text encoding** (an old .csv/.txt file in Windows-1252/Latin-1, common in older Spanish-language point-of-sale systems, is decoded correctly instead of showing dish names with broken accented characters).

11 Settings, currency and language

Settings is a window, not a page of its own — it opens from any screen.

11.1 Settings tabs

- **Profile** — name, email (changing it requires confirming the current password), country, type of business.
- **Appearance** — light / dark / system mode, and theme color.
- **Regional** — country (determines currency), and interface language.
- **Notifications** — email, push and SMS delivery preferences.
- **Developer** (account owner only) — export/import a data backup, reset local data.

11.2 Currency

21 supported currencies. Changing the currency **only changes the symbol and the display format** — it doesn't perform any real exchange-rate conversion on amounts already saved.

HNL — Lempira (L)

GTQ — Quetzal (Q)

CRC — Colón (₡)

NIO — Córdoba (C\$)

PAB — Balboa (B/.)

BZD — Belize Dollar (BZ\$)

USD — Dollar (US\$)

EUR — Euro (€)

CNY — Yuan (¥)

DKK — Danish Krone (kr)

MXN — Mexican Peso (\$)

ARS — Argentine Peso (\$)

COP — Colombian Peso (\$)

PEN — Sol (S/)

CLP — Chilean Peso (\$)

VES — Bolívar (Bs)

BRL — Real (R\$)

UYU — Uruguayan Peso (\$)

PYG — Guaraní (₲)

BOB — Boliviano (Bs)

DOP — Dominican Peso (RD\$)

11.3 Language

6 interface languages: Español, English, Dansk, Français, Português, 中文. Changing the language only translates the app's text — the currency format depends on the chosen currency, not the language, and the two settings are completely independent of each other.

12 Formula glossary — quick reference

Every formula in the manual, in one place, so you don't have to reread each section to look one up.

CONCEPT	FORMULA
Extended cost of an ingredient	$\text{quantity} \times \text{unit cost}$
Production Cost	$(\Sigma \text{ extended costs}) \times \text{PAX multiplier}$
PAX Multiplier	$\text{desired PAX} \div \text{declared yield}$
Yield by weight (estimated)	$\Sigma \text{ quantities in g/ml/kg/l}$
Effective yield	$\text{declared yield} \times \text{PAX}$, or yield by weight if none declared
Unit Cost	$\text{Production Cost} \div \text{Effective yield}$
Sale price (6 categories)	$\text{round_up_to_5}(\text{Unit Cost} + \text{Unit Profit})$ – always up, never to the nearest
Sale price (Food Cost %)	$\text{round_up_to_5}(\text{Unit Cost} \div (\text{target \%}/100))$ – always up, never to the nearest
Total Sale Price	$\text{Final price} \times \text{Effective yield}$
Contribution Margin	$(\text{Total Sale Price} - \text{Production Cost}) \div \text{Total Sale Price} \times 100$
Food Cost %	$\text{Production Cost} \div \text{Total Sale Price} \times 100$
Net Profit (total)	$\text{Total Sale Price} - \text{Production Cost}$
Allocated fixed cost / dish	$\text{monthly fixed expenses} \div \text{estimated monthly dishes}$
Usage Cost (sub-recipe)	$\text{Total Cost} \div \text{Yield}$
Suspicious yield warning	$\text{max. quantity in "unit"} \geq \text{yield} \times 20$
Inventory status	$\text{critical if stock} \leq \text{minimum} \cdot \text{low if stock} \leq \text{minimum} \times 2$
Total inventory value	$\Sigma (\text{current stock} \times \text{price})$
Suggested quantity (auto-purchase)	$\text{max}(\text{minimum} \times 2 - \text{current stock}, \text{minimum})$
Packages to buy	$\text{ceiling}(\text{quantity needed} \div \text{net content})$
Order line cost	$\text{quantity (base unit)} \times \text{base unit price}$
Purchase order total	$\Sigma \text{ line costs} \times (1 + \text{tax \%}/100)$
Menu Average Price	$\Sigma \text{ prices of active dishes} \div \text{no. of active dishes}$

ABOUT THE 6-CATEGORY METHOD'S DEFAULT PERCENTAGES

The Recipe Sheet form starts with Utilities 10% · Marketing 10% · Operational Costs 30% · Labor Costs 25% · ISV 0% · Net Profit 30% — these are the values you'll see on a new recipe with no prior business configuration. If your business has already saved its own costing method (section 02.1), those percentages replace these defaults.

13 Troubleshooting

The six most common "this isn't doing what I expected" cases — with the real cause, verified against the code, not a guess.

IF YOU SEE THIS...	IT'S PROBABLY...	WHAT TO CHECK
A recipe's numbers look absurd (sky-high cost or ridiculous price)	A misdeclared Yield, the wrong unit on an ingredient, or a sub-recipe whose quantities were meant for its own yield, not the yield of the recipe using it	Check the yellow suspicious-yield warning (05.4), and if you use sub-recipes, the note in 06.5.
You changed an ingredient's price and your recipes' cost didn't move	The chain recalculation (04.5) is automatic and immediate — if it doesn't show, the edited ingredient is probably not exactly the one the recipe uses	Confirm in the Recipe Sheet that this line uses the ingredient you edited, not a duplicate with a similar name.
You don't see a module that should be there (Finance, Team, Inventory...)	The account's plan doesn't include it, or — if you're in through a team invite — the owner didn't grant you that tool	The app shows two different messages for these cases (02.4): "your plan doesn't include this" vs. "the owner restricted this for you".
You marked a Purchase Order "Received" and inventory didn't change	That's expected — "Received" is only an order status, it never moves stock by itself (08.1)	Follow the recommended flow: record what came in under Inventory → New Purchase (08.1).
You edited the Yield by hand with PAX active, used "Restore" and lost that change	Expected behavior — Restore always goes back to the frozen original, ignoring any edit made afterward (05.10)	There's no way to recover it after Restoring; to keep a manually edited Yield, save it with PAX at 0 (05.10).
You saved a recipe with PAX active by mistake	The base yield already changed permanently, with your prior confirmation (05.10)	Use "Restore original recipe" and save again to confirm the reversal.

This manual was written by reading GastroMetrics's source code directly — every formula, fixed list and business rule described here corresponds to the actual logic implemented in the application at the time of writing, not to an approximate marketing description. If a

screen changes in a future version, this document may become outdated on that specific point.
